Solution for The CDMC 2017

Yuki Maruno, Ayumi Hirao, Mayu Nishimoto,
Midori Sakai, Marie Ohki

Abstract

The CDMC 2017 is a competition focusing on real-world problems regarding cybersecurity. We took part in this competition and our team was the first place winner. In this paper, we describe how we solved the following tasks with the provided dataset. We used the Random Forest classifier for all the tasks with the hyperparameter optimization and the feature selection. Experiments showed that our proposed method can obtain an accuracy more than 90% without high computational costs.

Key words：Data Mining Competition, APK Malware, Incident Detection, Fraud Detection, Random Forest

1　Introduction

The 8th International Cybersecurity Data Mining Competition (CDMC 2017) is a challenging, multi-month research and practice competition, focusing on application of knowledge discovery techniques to solve advanced, real-world problems. The competition is associated with the 10th International Workshop on Data Mining and Cybersecurity (DMC2017), which is an associated event to the 24nd International Conference on Neural Information Processing (ICONIP2017), Guangzhou, China.

In this competition, participants are required to solve all of the following tasks, Task 1: Android Malware Classication based on API information, Task 2: Incident Detection over Unied Threat Management (UTM) operation on UniteCloud, and Task 3: Fraud Detection in Financial Transactions. The following sections describe our solution in detail.

2　Task 1: Android Malware Classication based on API information

2.1　Task Description

Software vulnerabilities such as viruses, malware, and other attacks have serious security implications. Android Malware classi cation is needed to protect our device because of the rapid growth of malware threats for android platform [1].

To install software on the Android operating system, application package (APK) les are used,

which includes API (Application Program Interface) information.

The objective of this task is to design a classi er for malware detection based on the API information. A list of APIs obtained by reverse engineering the APK les were provided for the task. The APK les were collected from the Opera Mobile Store [2] over the period of January to September of 2014. The class label of the APK le was determined by the detection results of security appliances hosted by VirusTotal [3]. Adware was not counted as malware in the setting.

The information of the dataset is summarized in Table 1.

2.2 Our Proposed Method

Table 2 shows the example of the API names. The dataset for the task has 37,107 features (APIs) and two labels(1 and -1). 1 stands for a malware and -1 for a benign le. For preprocessing, we separated the API names by a dot character. For example, 'android.accounts.abstractaccountauthenticator.init' returns 'android', 'accounts', 'abstractaccountauthenticator' and 'init'. We only used the last one ('init') as the feature. Some of them are the same name. After preprocessing, we have 10,058 features in total.

We used the Random Forest (RF) classier with Python scikit-learn [4]. We tuned its hyper parameters to enhance the accuracy of the model. We have selected the best set of hyper parameters for RF. We trained our model data with the hyper parameters. Table 3 shows the list of hyper parameters we used in our experiments.

2.3 Experimental Results

We used 10 fold cross validation to compute the accuracy. In our experiments, we got the accuracy

3　Task 2: Incident Detection over Unied Threat Management (UTM) operation on UniteCloud

3.1　Task Description

The incident detection is important for Cloud environments since potential attacks and platform vulnerabilities can pose serious security threats to computers and networks. The objective of this task is to identify various incident accurately from the sensor log les captured from real-time running Unied Threat Management (UTM) on the UniteCloud server [5]. The information of nine selected sensors under the UTM platform was provided [6]. The class label of the log les was determined by incident status determination over the collected log data.

The information of the dataset is summarized in Table 6.

3.2　Our Proposed Method

Table 7 shows the example of the data. The dataset for the task has nine features and two labels (pass, block). For preprocessing, we lled NaN values with 0. V1, V2, V3, V4, V5 and V6 are categorical variables, and the others are continuous.

We excluded V1, V4 and V5.We converted each categorical variable into dummy variables. Table 8 shows the example of the converted V3. The 'gOqV' feature was also excluded because it is not appeared in the test data. After preprocessing, we have 15 features in total. We used the RF classier with Python scikit-learn.

We tuned its hyper parameters to enhance the accuracy of the model. We have selected the best set of hyper parameters for RF. We trained our

4 Task 3: Fraud Detection in Financial Transactions

4.1 Task Description

Financial fraud is a long standing issue with broad reaching consequences. The goal of this task is to design a classi er for fraud detection based on the nancial transaction. The original anonymized data was provided by the nancial institution [7], and was synthesized with highly correlated rule based uniformly distributed synthetic data (HCRUD) technique.The transactions from various account and transaction types were provided with 12 features for each transaction. The information of the dataset is summarized in Table 12.

4.2 Our Proposed Method

Table 13 shows the example of the data. The dataset for the task has 12 features and three labels (Non, Fraud, Anon). For preprocessing, we lled NaN values with 0, and 0+5i with 1. V1, V3, V10, V11 and V12 are categorical variables, and the others are continuous. We converted each categorical variable into dummy variables. After preprocessing, we have 32 features in total. We used the RF classier with Python scikit-learn. We tuned its hyper parameters to enhance the accuracy of the model. We have selected the best set of hyper parameters for RF. We trained our model with the hyper parameters. Table 14 shows the list of hyper parameters we used in our experiments.

4.3 Experimental Results

We used 10 fold cross validation to compute the accuracy. In our experiments, we got the accuracy of 0.978 with a validation dataset. Table 15 is a confusion matrix of a validation dataset. We also calculated the accuracy of the whole training data with the best model trained the parameters listed in Table 14.

We got the accuracy of 0.999. Table 16 shows a confusion matrix of the whole training data.

5 Conclusion

We took part in the CDMC2017 competition, and our team got the rst place winner. For all the tasks, we adopted the Random Forest classier commonly used in machine learning. Our hyper-parameter tuning and feature selection enhanced classication accuracy, which is high enough for real-world problems.
